Ryall and Bramson's Inference and Intervention is the first textbook on causal modeling with Bayesian networks for business applications. In a world of resource scarcity, a decision about which business elements to control or change – as the authors put it, a managerial intervention – must precede any decision on how to control or change them, and understanding causality is crucial to making effective interventions.

Causal inference goes beyond prediction by modeling the outcome of interventions and formalizing counterfactual reasoning. In this blog post, I provide an introduction to the graphical approach to causal inference in the tradition of Sewell Wright, Judea Pearl, and others. We first rehash the common adage that correlation is not causation.

Although observations allow drawing inferences about causes and effects of the observed event, interventions cut the event off from its causes by deleting the causal links pointing toward the event. Sloman and Lagnado (2005) coined the term undoing for this process. CAUSAL REASONING THROUGH INTERVENTION⁹¹.

We term these models population intervention models. The estimating equation approach provides a convenient mathematical method for deriving a class of estimators for a wide variety of causal inference problems. However, before applying the machinery (van der Laan & Robins, 2002), one must first define the parameter of interest.

Potential outcomes framework (Rubin causal model), propensity score matching and structural causal models are, arguably, the most popular frameworks for observational causal inference. Here, we focus on the structural causal models and one particular type, Bayesian Networks. Interested users can find more details in the references below.

A causal model on the counterfactual distributions of interest can be specified directly (and need not be graphical) 2, 11, 12, 25 or, alternatively, it can be derived by representing the counterfactual intervention of interest as an intervention on the graph (or set of equations). The initial structural causal model describes the set of processes that could have generated (and thus the set of possible distributions for) the observed data.

The most important aspect of inferring causal effects from observational data is the handling of confounders, factors that affect both an intervention and its outcome. A carefully designed observational study attempts to measure all important confounders.
