This is an interesting series-parallel circuit problem to solve, and it shows once again how a good understanding of circuit theory enables unmeasured variables to be inferred. Students often have difficulty formulating a method of solution: determining what steps to take to get from the given conditions to a final answer.

To solve these type of problems, usually the best way to start is to look at the far side of the circuit opposite to where RAB is. What the equivalent resistance you're looking for is and if that's not the place to start, then what you want to do is you want to look for something that looks easy to combine in terms of either series or a

Resistors network. RAB is measured at the left-most side of the circuit and the circuit contains this parallel and series combination of resistors. So we look at the circuit and we start by trying to find the easiest components to combine together. And if we look at that, in the right-most side of the circuit we see that we have a three kilo-ohm in series with a six kilo-ohm resistor.

The two resistors that are in parallel are grouped as Req2 in the equivalent circuit below and their resistance is given by the equation $1 / \text{Req}_2 = 1 / 100 + 1 / 200$ Solve to obtain $\text{Req}_2 = 200 / 3 \Omega$ Req1 and Req2 are in series and therefore are equivalent to R given by the sum $R = \text{Req}_1 + \text{Req}_2 = 500 + 200 / 3 = 1700 / 3 \Omega$
